AUTHORS: TITLE:

The Analysis of Electron-Flow Interaction with a

Travelling Wave

PERIODICAL: Radiotekhnika i elektronika, 1960, Vol 5, Nr 4,

pp 700-704 (USSR)

ABSTRACT:

In the assigned field approximation, it is usually assumed that the HF-field intensity in the delay line varies exponentially. However, in this approximation, it is not possible to study the signal behaviour in the initial part of the tube. In the present note the form of variation of the HF-field amplitude along the tube is not preassigned but is determined from the equation of balance of real power. It is assumed that the field in the line may be represented by a single wave with constant face velocity. The results of the study permit the value of gain to be estimated. There are 4 figures and 8 references, 6 of which are Soviet, 1 English and 1

Approximate Analysis of Type O BWT Operation TITLE:

PERIODICAL: Radiotekhnika i elektronika, 1960, Vol 5, Nr 6,

pp 1010-1012 (USSR)

ABSTRACT: The method used in Ref 6, consisting in finding the amplitude distribution of the HF-field intensity along

the tube in a BWT from the equation of real power balance, is used in the present communication to

analyse a type 0 BWT. The method also permits taking into account approximately the line attenuation as was

done in Ref 6.

TWT amplification with finite values of the gain

parameter C

PERIODICAL: Radiotekhnika i elektronika, Vol.6, No.1, 1961,

pp. 170-175

TEXT: The propagation constants in a TWT are expressed by an equation of fourth degree with complex coefficients. To simplify this equation it is usually assumed that the amplification parameter C introduced by Pierce is much smaller than unity. However, in medium and high power tubes C may reach values of 0.1 - 0.2. The energy method previously proposed by the present authors (Ref. 4: Radiotekhnika i elektronika, 1960, Vol.5, No. 4, 700) permits a simple solution of the problem at finite values of the parameter C. The article presents various graphs, of interest in TWT theory, based on this solution. There are 8 figures and 6 references: 4 Soviet and 2 English.

Tseytlin, M.B., and Il'ina, Ye.M. AUTHORS:

The configuration of the field in a backward wave tube TITLE:

in the presence of distributed attenuation

PERIODICAL: Radiotekhnika i elektronika, v. 6, no. 5, 1961, 826 - 828

TEXT: In their earlier work (Ref. 1: Radiotekhnika i elektronika, TEXT: in their earlier work (Ref. 1: Radioteknnika 1 elektronika, 1960, 5, 6, 1010) the authors gave an analysis of the operation of a backward wave oscillator. In the present article, they generalize the previous analysis extending it to a backward wave oscillator with losses. The equation for the balance of power in presence of attenuation in the tube, by analogy with Eq. (18) of another of the authors' works (Ref. 2: Radiotekhnika i elektronika, 1960, 5, 1960, 4, 700) will have the shape of

(1) $E_1(x) dx \int_{-\infty}^{\infty} E_1(t) \sin k (x-t) \sin \beta_q (x-t) dt -$

stituting into Eq. (4), the initial conditions

(6)

 $C_{1} = \frac{2km + \lambda_{02}\lambda_{03}\lambda_{04}\beta_{e}Cd - (\lambda_{03}\lambda_{04} + \lambda_{02}\lambda_{03} + \lambda_{02}\lambda_{04}(\beta_{e}Cd)^{2})}{\lambda_{01}(\lambda_{04} - \lambda_{01})(\lambda_{03} - \lambda_{01})(\lambda_{04} - \lambda_{01})}$  (6)

 $C_2$ ,  $C_3$ ,  $C_4$  are determined by cyclically changing the indices  $C_{2,1} = \sum_{i=1}^{4} c_{i}.$ (7)

The distribution along the tube of the relative amplitude of HF field intensity for different values of parameter d and for a neglibility small space charge (QC = 0) is shown. A similar dependance for the space charge (QC = 0.25) is also given graphically. The presence of maximum can be explained as follows: The field amplitude in the absence of losses varies according to a nearly cosinustial law, i.e. at the beginning of the tube it remains practically constant. The attenuation of the "cold" wave along the line is exponential and its amplitude decreases along the direction of the energy stream. It follows that the power stream of losses increasing

TITLE: Theory of cylindrical M-type beam instruments and the effect of space charge

SOURCE: IVUZ. Radiotekhnika, v. 9, no. 3, 1966, 316-326

TOPIC TAGS: electron amplifier, space charge, electron gun, radial beam tube

ABSTRACT: The theory of small signal amplifiers with a rotating electron beam formed by an electron gun, and with crossed-over electric and magnetic fields is presented. A disperison equation is derived from which, as a special case, known results for the E- and M-types of amplifier are determined. The bunching process in such amplifiers is compared. Special attention is given to cylindrical M-type amplifiers operating in large magnetic fields. The field of the space charge is considered for the care when the line walls are spaced either very far apart from or very close to the flat beam. Certain abnormal relationships are described between the amplification in M-type instruments and generalized parameters resulting from the instrument's non-planar structure. Orig. art. has: 4 figures and 20 formulas.

TOPIC TAGS: traveling wave tube, traveling wave interaction, helical spring, calculation, approximation calculation, ELECTRON FLOW PURPOSE AND COVERAGE: This book develops the theory of traveling-wave tubes by incorporating the newest concepts of Soviet and other scientists. It is concerned primarily with electron flow and traveling wave interaction at high-value amplification factors as applied to medium- and high-power tubes. The text also includes a detailed study of the effect of a local absorber and of reflections from matching devices on traveling-wave tube characteristics, and an analysis of traveling-wave tube per-

marily with electron flow and traveling materials. The text also includes a detailfactors as applied to medium- and high-power tubes. The text also includes a detailed study of the effect of a local absorber and of reflections from matching devices
on traveling-wave tube characteristics, and an analysis of traveling-wave tube performance at ultimate levels of signal input. It also contains methods for calculating
formance at ultimate levels of signal input. It also contains methods for calculating
the basic parameters of helix-type traveling-wave tubes. The book is based on previous research carried out by the authors in collaboration with Ye.M. Il'ina, I.A.
vious research carried out by the authors in collaboration with Ye.M. Il'ina, I.A.

Abstract : An insufficient amount of fruit-bearing shoots and a low coefficient of Truit-bearing in a series of Central-Asiatic va-

rieties of grapes seriously impairs efforts towards increasing yields. The author and other researchers have ascertained that eff-shoots developed after a timely pinching of the basic vines result in increased fruit-bearing (200 percent in varieties Khusain and 125 percent in the variety Kishmish white). Off-shoots developed well, riponed and and appeared to be endowed with greater winter-hardiness than

the basic shoots. By leaving the basic shoots together with

Abstract : In insufficient ovulation of berries is often observed in

varieties of the female function, as well as in varieties of both sexes of groups, which is due to sterility of the pollen, to its poor transfer or to non-germination. This hads to a decrease in crops. Cross pollination of various species and with one single specie favorably influences the ovulation of berries and promotes an imcrease in their size. For the purpose of securing a better ovulation, additional arti-

ficial pollination is carried out with a pollen mixture favoring an increase in the amount of borries, in the amount

of their seeds and in their weight and size. According to

Rol' perekisey i kisloroda v nachal'nykh stadiyakh radiobiologicheskogo effekta (Role of Peroxides and Oxygen During Primary Stages of Radiobiological Effects) Moscow, 1960. 157 p. 4,500 copies printed.

Responsible Ed.: A. M. Kuzin, Professor; Ed. of Publishing House: K. S. Trincher; Tech. Ed.: P. S. Kashina.

PURPOSE: This collection of articles is intended for scientists in radiobiology and biophysics.

COVERAGE: Reports in the collection deal with the role of peroxides and oxygen in the primary stages of a radiobiological effect. They were presented and discussed at a symposium held December 25-30, 1958, organized by the Institut biofiziki AN SSSR, (Institute of Biophysics, AS USSR). Twenty-eight Moscow scientists, radiobiologists, radiochemists, physicists, and

Selection of Parameters for Basic Electrical Devices of Centralized Power Systems of Lumber Industries (Vybor parametrov osnovnykh elektricheskikh ustroystv dlya tsentralizovannogo elektrosnabzheniya lesozagotovitel'nykh predpriyatiy)

PERIODICAL:

Tr. Tsentr. n.-1 in-ta mekhaniz. 1 elektr. les. prom-st1, 1956, Nr 3, pp. 90-108

ABSTRACT:

Typical circuit diagrams of power supply from the local power station and from the regional network are given. Given are formulae and graphs showing voltage loss per km depending upon the load, conductor cross section and power factor. Tables listing voltage losses for steel conductors are included. From total voltage losses of 10% which includes the step-up transformer, it is suggested that 2 to 2.5% be allotted for temporary taps increasing when necessary the generator voltage by 2.5 to 3% above the rated. Also given are tables for

CIRCUITS

"Frequency Dividers Employing Transistors", by M.Z. Tseytlin, Elektrosvyaz', No 9, September 1957, pp 33-41.

Description of regenerative transistorized frequency dividers using junction and point-contact transistors. This circuit contains a frequency multiplier in the feedback loop and is similar to the vacuum-tube equivalent circuit. The application of the circuit is described and an experimental verification of the theoretical premises is given. The circuit is found to give reliable frequency division at a division coefficient from three to ten and above. The divider operates reliably with supply voltages ranging from five to 40 volts. The tolerance in the circuit parameters increase from 2 - 2.5% at n = 0 (n is the frequency division coefficient) to 4 - 10% at n = 3.

Another circuit described in this article is a regenerative frequency divider employing a ferrite peak transformer, in accordance with the circuit proposed by V.M. Rozov (Elektrosvyaz', June 1956), which can raise the frequency division coefficient to 14 -- 16. It is shown that a divider with a peak transformer is more economic and consumes less power than a circuit employing two junction transistors.

and  $\beta$  are constants determined by the where

Cardl/4

Wide-band Frequency Dividers with a Changeover Switch in the Feedback Circuit

circuit parameters; v(t) is a unit switching function, equal to +1 when the feedback voltage is positive and -1 when it is negative. If an amplifier with a high input impedance is used, then  $R_1 \ll R_{\rm BX}$ ,  $r_n \ll r_3$ ,  $R_i \ll r_3$  ( $R_i$  and  $R_{BX}$  being as shown in Figure 3), and:

$$\alpha \approx \frac{1}{2} \cdot \frac{1 + 2\frac{r_n}{R_i}}{\frac{r_n}{1 + \frac{r_n}{R_i}}}; \quad \beta \approx \frac{1}{2} \cdot \frac{1}{\frac{r_n}{R_i}}$$
(8) .

If  $R_i$  is less than  $r_n$ , the frequency divider becomes ineffective. In this case, the modulator must be connected in series instead of in shunt (Figure 4). Because the resistance  $r_n$  is comparable with the input Card2/4

Wide-band Frequency Dividers with a Change-over Switch in the Feedback Circuit

resistance of a semiconductor triode, the valve in Figure 1 cannot be replaced by a semiconductor triode without modification of the circuit. A suitably modified circuit using a second semiconductor triode instead of a ring modulator was developed and the circuit is given in Figure 5. In the experimental work it was found that the frequency was changed not only by an even number of times but also by an odd number. This can be due to a number of causes: non-linear amplification, difference in rectifier characteristics, etc. In the subsequent analysis, the amplifier is considered linear and the relationships which give even division are investigated. The relationships 1) the output amplitude of the frequency divider bears a

linear relation to the input amplitude;

2) the greater the slope of the amplifier and the greater the modulation depth of the input signal, the greater will

3) the secondary (feedback) circuit reduces the resonant

Uard3/4

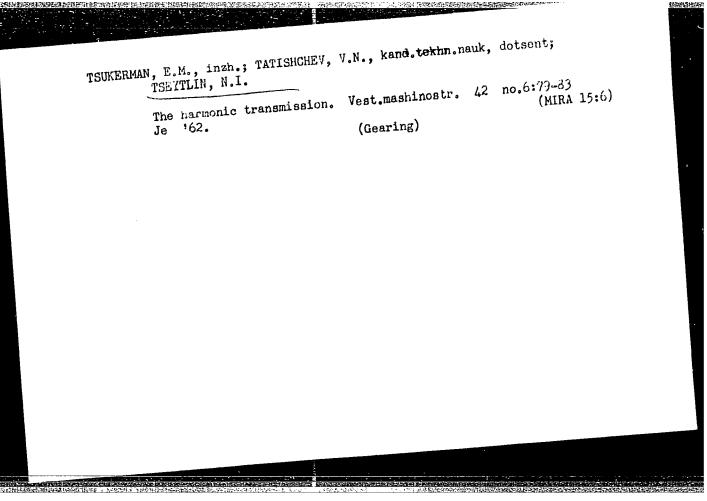

Wide-band Frequency Dividers with aChange-over Switch in the Feedback Circuit

frequency of the primary circuit; 4) except under certain specified conditions, the frequency characteristics will be unsymmetrical. The synchronisation bandwidth is investigated analytically The synchronisation bandwidth is investigated analytically and found to depend on the coupling between the primary and secondary circuit and on the Q of the secondary circuit. The results are illustrated graphically. The results of experimental investigation are given. There are 19 figures, 1 table and 7 references, 5 of which are Soviet and 2 Facilish 2 English.

Tseytlin, N.M.

Measurement of the Efficiency and Directivity of an Antenna at Metre Waves by Means of Extra-terrestrial

Izvostiya vysshikh uchebnykh zavedeniy, Radiofizika, Radio Radiation 1958, Vol 1, Nr 5-6, pp 105 - 111 (USSR) PERIODICAL:

ABSTRACT: V.S. Troitskiy (Ref 1) proposed and theometically justified a method of measuring the directivity of antennae on the

basis of their natural noise and of the distributed cosmic This article is concerned with the application of the method to the range of metric waves. The cosmic

radiation consists of a continuously distributed noise (the background noise) and the radiation of discrete

sources. By using the radiation of the background it is possible to determine the losses in an antenna, while by

means of the radiation of a discrete source one can determine its directivity (Ref 1). If the cosmic radiation

is received from a direction determined by angles  $\phi_0$ 

which do not contain a powerful discrete source, the Card1/4

CIA-RDP86-00513R001757020007-2" APPROVED FOR RELEASE: 03/14/2001

06471

SOV/141-1-5-6-15/28
Measurement of the Efficiency and Directivity of an Antenna at Metre Waves by Means of Extra terrestrial Radio Radiation

noise temperature  $T_{a}$  at the matched load of the antenna is given by:

$$T_{\mathbf{a}} = T_{\mathbf{c}p}(\varphi_{\mathbf{o}}, \psi_{\mathbf{o}}) \eta + T_{\mathbf{o}}(1 - \eta) + \Delta T(\varphi_{\mathbf{o}}, \psi_{\mathbf{o}}) \eta \tag{1}$$

is defined by Eq (2). The symbols in the equations are as follows:

is the main lobe of the directional pattern of the antenna;

is the overall antenna pattern;  $F^2(\Omega)$ 

is the background noise temperature;  $T(\Omega)$ 

is the temperature of the material of the

antenna (determining its own noise); is the efficiency of the antenna and

is the average temperature of the antenna when receiving the radiation from the regions lying ΔΤ

outside the main lobe.

Card2/4

Measurement of the Efficiency and Directivity of an Antenna at Metre Waves by Means of Extra-terrestrial Radio Radiation

If  $\Delta T$  can be neglected,  $\eta$  can be determined from Eq (3), provided T is known. The directivity of the cp antenna can now be determined by measuring the intensity of the radiation of a discrete source having an intensity  $S_{\gamma}$  and producing an average temperature  $T_{cp}$ . The directivity can be determined from Eq (4), where D denotes the directivity. The values  $\eta$  can be determined most accurately by measuring the radiation temperature difference between two regions having widely differing temperatures. For this case, Eq (1) can be written as Eq (5). Since the second term in Eq (5) can be neglected, the temperature difference can be expressed by Eq (6). Similarly, the most accurate values of the directivity can be obtained by measuring the temperature difference between a region containing a discrete source and a standard known region without a source. For this case, Eq (4) can be written as Eq (8). The most suitable radiation source for this Card3/4 measurement is Cassiopeia-A and Cygnus-A. The above method

THE WAS THE PROPERTY OF THE WAS TRANSPORTED BY THE WAS THE WAS

S0V/141-1-5-6-15/28 Measurement of the Efficiency and Directivity of an Antenna at Metre Waves by Means of Extra-terrestrial Radio Radiation

was used to determine the directivity of antennae at the wavelengths of 1.5 m and 3 m. From the measurements, it was concluded that the efficiency could be determined with an error of about 10% and the directivity with an error of 15-20%; these figures are valid for the wavelengths of 1-5 m and the antenna beam widths of 10-15°. The author expresses his gratitude to V.S. Troitskiy for directing this work. There are 2 figures, 1 table and 8 references, of which 2 are English, 5 are Soviet and 1 German.

AUTHOR: Izvestiya vysshikh uchebnykh zavedeniy, Radiofizika, TITLE: 1959, Vol 2, Nr 5, pp 677 - 682 (USSR) ABSTRACT: The equivalent circuit of a receiving antenna is in the PERIODICAL: form shown in Figure 1. This consists of a source having  $^{2}_{ ext{f}}$  , a load impedance  $z_{ ext{H}}^{ ext{}}$  and an internal impedance  $z_a = R_a + jX_a$ . It is shown that the e.m.f. can an e.m.f. be expressed by:  $\overline{e_f^2} = 4R_a k \left[ T_o \gamma_a + T_{\Sigma} (1 - \gamma_a) \right] = 4R_a k T_a$ (1)where  $\gamma_a = R_{fr}/(R_Z + R_{fr})$ , k is the Boltzmann constant, Re is the radiation impedance of the antenna  $R_{\Pi}$  is the loss resistance of the antenna. Card1/6

S/141/59/002/05/001/026

The Calibration of Radio-astronomical Equipment Eq (1) is true for any receiving antenna. By employing the circuit of Figure 1, it is possible to determine the power spectrum density in the presence of a non-matched load, which is connected to the antenna by a line. The equivalent circuit in this case is shown in Figure 2. The spectral density of the noise at the points cd is now given by (Ref 7):

$$\frac{1}{e^{2}} = kT_{a} e^{-\gamma_{3}} A_{1} + kT_{3} e^{(1 - e^{-\gamma_{3}})} A_{2} + kT_{4} e^{A_{3}}$$
(4)

where  $T_{\mathfrak{I}}$  and  $T_{\widetilde{H}}$  are the temperature of the line and the load, respectively, Q is the wave impedance of the line and  $\gamma_{JJ} = 2\alpha l$ . The coefficients  $A_1$ ,  $A_2$ represented by Eqs (5), where  $p_a$  and  $p_H$  are the reflection coefficients for the antenna and the load, while

The Calibration of Radio-astronomical Equipment

 $\alpha_1 = \alpha + j\beta$  is the propagation constant. spectrum density at the load is given by Eq (6). If the measurements are carried out by means of a radiometer, the reading of the output meter,  $\beta$ , is proportional to the difference of the spectral densities of a "cold" power  $W_{X}$  , and of the antenna system  $W_{H}$  . During the calibration, the indication  $\alpha$  of the output meter standard, is proportional to the difference of the spectral density from/"hot" standard, Wr , and from the "cold" standard.

The ratio  $\beta/\alpha$  is expressed by Eq (8). During the measurement of the strength of the sources or the relative strength of a distributed cosmic source, it is usual to determine the power difference between the investigated and the "standard" region of the sky.

The corresponding readings of the output meter of the and  $\beta_2$  . The relationship between radiometer are  $\beta_1$ 

is expressed by Eq (9). these quantities and  $\alpha$

The Calibration of Radio-astronomical Equipment/E382

shown that, in practice, Eq (9) can be simplified and shown that, in practice, Eq (10) is the temperature written as Eq (10), where  $\Delta T_{\Sigma}$  is the temperature

difference between the measured region and the standard region of the sky,  $\eta_A$  is the efficiency of the line and

 $\eta_a$  is the efficiency of the antenna. If a noise diode is used for the calibration, Eq (10) can be written as Eq (11). The product  $\eta_{\eta_a}^{\eta_a}$  in Eqs (10) and (11) can

be measured by the method described in Refs 2 and 8. At metre waves, the coefficient  $\eta$  is determined from the difference in the strength of the cosmic radiation from two calibration regions of the sky. The coefficient is expressed by Eq (12). Consequently, the strength of the source (on the basis of Eq 11) can be expressed by Eq (15), where  $K_1$  is a coefficient taking into account

the mismatch of the noise generator and I is the current of the noise diode. It is seen, therefore, that at metre waves, it is possible to measure the strength of a source

s/141/59/002/05/001/026

The Calibration of Radio-astronomical Equipment

without the thermal calibration or the determination of the efficiency by measuring the radiation from a source and a standard region. At centimetre waves, the coefficient  $\eta$  is expressed by Eq (17) (Ref 2), where is the temperature of the zenith and  $\,\beta_{\,K}\,$ reading of the output meter during the measurement of the internal noise of the antenna. If the system is mismatched and  $T_0 = T_N$ , Eq (17) can be written as

Eq (18) or, approximately, as Eq (19). This expression is burdened with an error, the value of which is indicated in Table 1. If this error is permitted in the measurement, the temperature difference  $\Delta T_{\Sigma}$ 

From this, it is seen that at centimetre waves the measurement without the thermal calibration reduces the effect of the mismatch but does not completely eliminate it, as was the case with the metre waves. This is due to the fact that at metre waves the calibration is effected by means of an external source, while at centimetre waves

Tseytlin, N.M. AUTHOR:

The Problem of Noise and Efficiency of Antennae Izvestiya vysshikh uchebnykh zavedeniy, Radiofizika, TITLE:

1960, Vol 3, Nr 2, pp 257 - 268 (USSR) PERIODICAL:

ABSTRACT: First, a thin radiating metal resonator, having a radius a and a length 2L is considered. It is assumed that the radius is much smaller than 2L. The spectral

density of the natural noise on a matched load  $z_{\rm H}$ 

connected to the point  $s_0 = 0$  of the resonator rod is

given by (Ref 8):

 $P_{\omega B} = I_{\omega}^{2} (0) / z_{a} / ^{2/4}R_{a}$ (1.1)

where  $z_a = z_H = R_a + jX_a$  is the input impedance of the radiating rod,  $I_\omega^2(0)$  is the spectral density of the

average current squared at the point of connecting the load. The current distribution in the radiator is described by Eq (1.2) at non-resonant frequencies and

Card1/6

S/141/60/003/02/010/025 E192/E382

The Problem of Noise and Efficiency of Antennae

by Eq (1.3) at the resonant frequencies. In these equations  $P_1$  is the resistance of the rod and  $P_2$  is the resistance of the rod and  $P_3$  is the resistance of the rod and  $P_4$  is the where k is the Boltzmann constant and T is the temperature of the radiator). The noise density at the temperature of the resonant frequencies. If the temperature of the radiator is uniform and  $P_1$  is the resistive component of the impedance of where  $P_4$  is the resistive component of the impedance of a cylindrical conductor having the length  $P_4$  and the radius  $P_4$  is given by Eq (1.7). The efficiency of the radiator is defined by:

 $\eta = R_{\Sigma}/R_{a} \qquad (1.8) ,$ 

where  $R_a = R_z + R_h$ ; here,  $R_z$  is the radiation

Card2/6

S/141/60/003/02/010/023
E192/E382
The Problem of Noise and Efficiency of Antennae resistance of the radiator and  $R_{\Pi}$  represents the loss resistance. It is shown that the efficiency at nonresonant frequencies is described by Eq (1.16), while at the resonant frequencies it is given by Eq (1.17). Finally, the spectral density of the radiation noise and the efficiency can be expressed by:

where the constant A is defined on p 261. Eqs (1.18) are used to determine the losses  $\gamma_1$  in the radiator; the losses are defined as  $\gamma_1 = 1 - \eta_1$ . The losses for a steel radiator operating at T = 300  $^{\circ}K$  are estimated

Card3/6

s/141/60/003/02/010/13/

The Problem of Noise and Efficiency of Antennae in Table 1. An antenna situated in a cavity heated to a temperature  $T_{\eta}(\vartheta, \phi)$  is then considered. The radiation of a surface element ds of the cavity at a distance  $\tau$  from the antenna in the direction  $\phi_0$ ,  $\phi_0$ is captured by the antenna over the spherical angle or, where  $\sigma = (\lambda^2/4\pi) D (\mathcal{S}_0, \varphi_0)\eta$  is the effective capturing area of the antenna in the direction  $\sqrt[3]{}_0$ ,  $\phi_0$ ; D is the directivity of the antenna in the direction and  $\eta$  is the efficiency of the antenna system. It is shown by means of thermodynamic approach that for this case the spectral density of the power on the matched antenna load is given by Eq (2.5), the antenna being situated in a black cavity having a temperature  $T_0$ . The spectral density of the noise due to the thermal radiation of the passive elements of the antenna and the efficiency of the antenna (determined by the losses in the passive elements) are given by Eqs (2.7). These equations

Card4/6

S/141/60/003/02/010/025 E192/E382

The Problem of Noise and Efficiency of Antennae

can also be derived by employing the electrodynamic approach. It is shown that in this case the efficiency and the noise of the passive elements are given by Eqs (2.16), which coincide with Eqs (2.7). The losses in the (2.16), which coincide with Eqs (2.7). The losses in the antenna due to the passive elements are defined by Eq (2.17). The losses are evaluated for an antenna operating at various wavelengths and the results are given in Table 2. Eqs (2.16) can be employed to evaluate the noise due to the radiation of the soil. The induced thermal noise in antennae can be evaluated by employing the Kirchhof formula:

$$P_{\omega} = \frac{2\pi^2 n^2 I_{0\omega}}{k} \sum_{k} A_{\omega i}$$
 (3.1)

where  $A_{\omega i}$  are the energy absorption coefficients for various mutually orthogonal incident waves,  $I_{0\omega}$  is the equilibrium radiation in vacuum, n is the refraction index and  $k=2\pi/\lambda$ . Eq (3) can also be written as

Card5/6

S/141/60/003/02/010/025

The Problem of Noise and Efficiency of Antennae

Eq (3.3). Now if the radiated power, expressed by Eq (3.3), is received by a body (for example, an antenna) having an effective area  $\lambda$   $B_{\omega i}$  the spectral density of the

power absorbed by the body is expressed by Eq (3.4). The author expresses his gratitude to V.S. Troitskiy for suggesting the problem and discussing this work and to M.L. Levin and V.A. Razin for discussing this paper. There are 1 figure, 2 tables and 10 Soviet references.

The Measurement of the Intensity of Discrete Sources at Metre Wavelengths by Comparison with Distributed Cosmic

Radiation v

Izvestiya vysshikh uchebnykh zavedeniy, Radiofizika. PERIODICAL:

1960, Vol 3, Nr 2, pp 334 - 336

ABSTRACT: The calibration of a radio telescope usually requires a knowledge of the efficiency of the aerial, its mismatch and its polar diagram. At metre wavelengths, lack of precise knowledge of sidelobe structure introduces large errors. If the source intensity is measured with respect to regions of distributed emission only the main lobe of the aerial and the difference in mean temperatures of the "reference" regions need be known. Although absolute temperatures may not be known to better than 30%, relative values may be determined to within 5-10%. Expressions for the effective aerial temperatures when pointing at a discrete source and at two other regions are given in Eq (2). Hence, the intensity of the discrete sources is given by Eq (4). The values of the temperature differences may be

Card1/2

s/141/60/003/02/020/025

The Measurement of the Intensity of Discrete Sources at Metre Wavelengths by Comparison with Distributed Cosmic Radiation

found from isophot diagrams. Using this method, the intensity of Cassiopeia-A'has been measured at 100 Mc/s (aerial 26 x 26) and 207 Mc/s (15 x 20). The results were, for one polarization, respectively 100.10 and  $31.10^{-24}$  Wm  $^{-2}$ c  $^{-1}$ . The accuracy is only about 20-25%. As noted by other writers, the spectrum is weaker around 200 Mc/s (Refs 3-6). There are 6 references, 1 of which is Soviet and 5 are English.

KANDER BURNER BU

Method of Measuring the Scattering Coefficient and Background Noise of Antennae. Absolute Measurement of the Background Brightness at Ultrahigh Frequencies

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Radiofizika, 1960, Vol. 3, No. 4, pp. 667 - 671

TEXT: The conditions of measuring the background are first considered. It is assumed that the space surrounding the antenna is for a given wave characterised by a brightness temperature distribution  $T(\phi, \psi)$ , which should be measured by means of a radiometer having a radiation pattern  $F(\phi-\phi',\psi-\psi')$  where  $\phi'$  and  $\psi'$  are the azimuth and the height of the main beam of the artenna. The noise at the output of the antenna is given by:

 $T_{a}(\phi^{o}, \psi^{o}) = \bar{T}_{(0)}(\phi^{o}, \psi^{o})\eta(1-\beta) + \bar{T}_{b}(\phi^{o}, \psi^{o})\eta\beta + T_{o}(1-\eta) \quad (1)$ 

where  $\eta$  is the efficiency of the antenna,  $T_0(1-\eta)$  is the internal noise of the antenna and Card 1/6

S/141/60/003/004/011/019 E192/E382

Method of Measuring the Scattering Coefficient and Background Noise of Antennae. Absolute Measurement of the Background Brightness at Ultrahigh Frequencies

is the temperature of the body of the antenna. are defined by Eqs. (2) and and The temperatures represent the average intensity of the background contained in the main lobe and all the remaining lobes of the antenna, respectively; the parameter  $\beta$  in Eq. (1) represents the portion of the power radiated in the side lobes of the antenna. The first term of Eq. (1) represents the noise received by the main lobe of the antenna pattern, while the second term gives the power of all the remaining lobes. When measuring the background brightness it is necessary to determine the first term of Eq. (1). However, in order to avoid errors, it is necessary that the quantity  $T(\phi, \psi)$  be constant within the limits of the main lobe. The method proposed consists of measuring the radiation from three definite Card 2/6

S/141/60/003/004/011/019 E192/E382

Method of Measuring the Scattering Coefficient and Background Noise of Antennae. Absolute Measurement of the Background Brightness at Ultrahigh Frequencies

calibrating regions which can be arbitrarily situated in space. The true zenith is chosen as one of these calibration directions. The second direction is represented by the zenith "reflected" into the antenna by means of a flat mirror; the third direction is obtained by directing the antenna onto an absolutely dark surface situated together with the flat T . Both surfaces are mirror and having a temperature The antenna noise temperature,

when its main lobe is directed towards the zenith  $(\phi_1^{},\,\psi_1^{})$  ,

is given by Eq. (3). The noise temperature at the output of the antenna when it is directed onto a reflecting surface  $(\phi_2^{}$  and  $\psi_2^{})$  is given by Eq. (4), while the noise temperature, when the antenna is directed onto an absorbing surface having

the same coordinates  $\phi_2$  and  $\Psi_2$  , is defined by Eq. (5),

Card 3/6

55986 S/141/60/003/004/011/019 E192/E382

Method of Measuring the Scattering Coefficient and Background Noise of Antennae. Absolute Measurement of the Background Brightness at Ultrahigh Frequencies

where  $\bar{T}_{CS}$  and  $\bar{T}_{6}$  are determined from Eq. (2). Finally, the main lobe is directed towards the region whose temperature is to be determined (coordinates  $\phi_{X}$  and  $\psi_{X}$ ); the temperature is now given by Eq. (6). From Eqs. (4) and (5) it follows that  $\Delta T_{32}$  is given by Eq. (7), from which it is possible to determine  $\eta(1-\beta)$ ; this is given by Eq. (8). The temperature  $\bar{T}_{CS}$  is therefore given by Eq. (11). All

the quantities in this equation are known except  $\Delta$ ; however, in most cases,  $\Delta$  can be neglected. In order to determine the background noise it is necessary to introduce an additional measurement, namely, the noise at the output of the antenna is compared with the noise of a black body, which is substituted for the antenna. The temperature of the black

Method of Measuring the Scattering Coefficient and Background Noise of Antennae. Absolute Measurement of the Background Brightness at Ultrahigh Frequencies

body is  $T_o$ . By employing this measurement it is possible to determine approximately the quantity  $\eta$  (Eq. 14). It is then possible to determine  $\beta_1$  and a more accurate value of  $\eta$ . Finally,  $\bar{T}_1$  and  $\bar{T}_{32}$  can be found. From these, it is possible to determine the magnitude of the background noise. By employing the above method,  $\eta$  and  $\beta$  were measured for By employing the above method,  $\eta$  and  $\beta$  were measured for a 4 m paraboloid provided with a waveguide radiator. It was found that  $\eta=0.85$  and  $\beta=0.34$ . The quantity  $\beta$  was found that  $\eta=0.85$  and  $\beta=0.34$ . The quantity  $\beta$  was found that also determined by a different method and it was found that the two values were in good agreement. There are 3 references: 2 Soviet and 1 English.

TITLE:

A Method of Measuring the Dielectric Constant of

Lunar Soil

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Radiofizika,

1960, Vol.3, No.6, pp. 1127-1128

The dielectric constant of lunar soil has only been TEXT: measured at optical frequencies using observed values of Brewster's angle for reflected solar light. Owing to the irregularity of the surface under investigation, the angle cannot be determined very accurately, and the dielectric constant is found to lie between 2 and 2.5. The present authors suggest that the larger radio telescopes which are now available should be used to study the polarization of the radio emission of the moon. Such measurements could be used to determine the dielectric constant of the lunar medium at radio frequencies. The method suggested by the present authors consists in the measurement of the radio brightness for the horizontally and vertically polarized radiation from a chosen part of the lunar surface. Card 1/4

optical and radio values for the dielectric constants may be used to obtain information about the density of the surface material. The above discussion strictly applies only to the case of specular reflection. In reality, the reflections will be appreciably non-specular and the results will depend on the "roughness" of the surface. However, 8 mm experimental data (Ref.2) indicate that even in this wavelength region the specular effect is quite appreciable. There are 1 figure and 2 Soviet references.

TITLE:

Radioastronemical methods of measuring signal intensities and of calibrating antennae and radio-

telescopes in the centimetre band

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Radiofisika. 1961, Vol.4, No.3, pp.393-414

TEXT: This is a general review of accurate absolute methods for measuring signal intensities as is necessary, for example, in radio astronomy. The authors divide the methods into two groups. In the first, the calibration is by the internal noise of the antenna system. In the second, it is by an external radiation source (e.g. a black body). A "black body" in this context can mean an absorbing screen or a region of soil, weeds or sea. The authors consider the Moon to be the best "black bedy" to use; particularly if highly directional antennae are employed. They believe that the use of a "black body" together with reflecting mirror is superior to the use of the internal noise of the antenna. This is because the former method not only permits the Card 1/4

S/141/61/004/003/001/020 E133/E435

Radioastronomical methods ...

measurement of the radiation intensity but also of the overall absorption in the antenna system. It is also unnecessary to consider the background radiation with this method. On the other. hand, it is simpler, in practice, to use the internal noise. This method also permits the measurement of the scattering factor The authors suggest that the following investigations should be made in order to increase the accuracy of calibrating radio-(a) Study of the radio ... telescopes in the centimetre band.
